Class 08 - Breast Cancer Mini Project

Juliette Bokor (PID: A16808121)

About

In today's lab, we will work with fine needle aspiration (FNA) of breast mass data from the University of Wisconsin.

##Data Import

```
wisc.df <- read.csv("WisconsinCancer.csv", row.names = 1)
head(wisc.df)</pre>
```

Initial Analysis

Clustering

Before analysis I want to make a new data set, removing the first column (diagnosis), which is essentially the answer.

```
diagnosis <- as.factor(wisc.df$diagnosis)
#using as.factor stores the data as a "factor", shows the levels at the bottom
diagnosis</pre>
```

```
[556] B B B B B B B M M M M M M B
```

Levels: B M

```
wisc.data <- wisc.df[,-1]
head(wisc.data)</pre>
```

We can try a kmeans() clustering first

```
km <- kmeans(wisc.data, centers=2)
#to find how many are in each cluster using table()
table(km$cluster)</pre>
```

1 2 131 438

Cross-table

```
table(km$cluster, diagnosis)
```

#shows the number of malignant/benign in each cluster - this is not what we want; we want

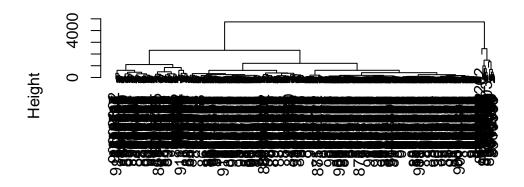

Let's try hclust() the key input required is a distance matrix as produced by the dist() function.

```
hc <- hclust(dist(wisc.data))</pre>
```

I can make the dendrogram

plot(hc)

Cluster Dendrogram

dist(wisc.data) hclust (*, "complete")

#this is not actually that useful, almost all the data is in a singular cluster, benign an

PCA

Do we need to scale the data?

We can look at the sd of each column (oirginal variable)

round(apply(wisc.data, 2, sd))

```

Generate our main PCA plot (score plot, PC1 vs PC2 plot)...

```
library(ggplot2)

res <- as.data.frame(wisc.pr$x)

#making a ggplot coloring by diagnosis, under aes instead of geom ggplot(res) +
   aes(PC1, PC2, col=diagnosis) +
   geom_point()</pre>
```

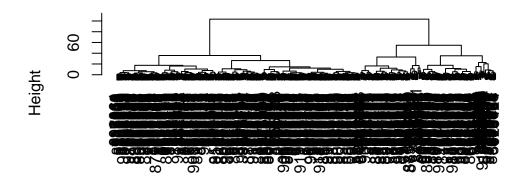

We see a visual separation of the two diagnoses based on a "line" when plotting PC1 vs PC2; it is separating out the cancer (malignant) from non-cancer (benign).

Combining Methods: Clustering on PCA results

Using the minimum number of principal components required to describe at least 90% of the variability in the data, create a hierarchical clustering model with the linkage method="ward.D2". We use Ward's criterion here because it is based on multidimensional variance like principal components analysis. Assign the results to wisc.pr.hclust.

```
#doing it on PC1-PC3, not all the PCs (first three columns), need it as a distance vector
#covering 90% of the variability would require us to plot PC1 through PC7.
d <- dist(wisc.pr$x[,1:3])
hc <- hclust(d, method="ward.D2")
plot(hc)</pre>
```

Cluster Dendrogram

d hclust (*, "ward.D2")

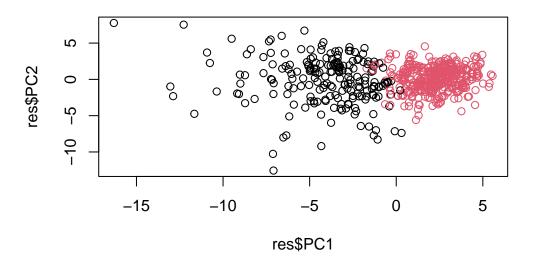

To get my clustering result/membership vector I need to "cut" the three with the cutree() function.

you can use the argument k= to define the number of branches you want to cut the tree in grps <- cutree(hc, h=80)

Q. How many patients are in each cluster group?

```
table(grps)
```

grps 1 2 203 366

Prediction

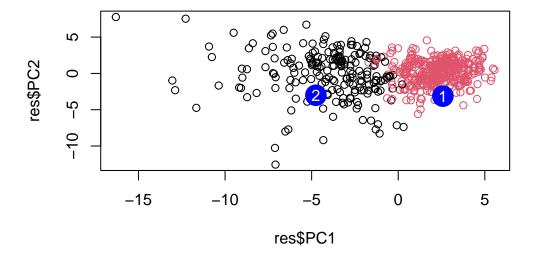

We can use our PCA result (model) to do predictions, that is take new unseen data and project it onto our new PC variables.

```
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(wisc.pr, newdata=new)
npc</pre>
```

```

Summary

Principal Component Analysis (PCA) is a super useful method for analyzing large datasets. It works by finding new variables (PCs) that capture the most variance from the original variables in your dataset.

Q17. Which of your analysis procedures resulted in a clustering model with the best specificity? How about sensitivity?

The hierarchical clustering of the PCA results has the best specificity and sensitivity of the analysis procedures that we ran.

Q18. Which of these new patients should we prioritize for follow up based on your results?

Patient 2 should be prioritized, they are in the cluster of the malignant data, indicating that they likely have a malignant cancer.
